Nibor Transparency Statement

No 13 – 30 April 2024

The information in this statement is unaudited and provided for illustration purposes only. The information may not be regarded as part of the provisioning of the interest rate benchmark Nibor, and the information cannot for any purposes be used as a benchmark.

Nibor Transparency Statement

Published 30.04.2024.

The Nibor Transparency Statement has been introduced with the purpose to provide users of Nibor with information about the data which the fixings of Nibor have been based on. The statement presents some key figures underlying the Nibor fixings, including the Nibor Transparency Model for the Nibor three months tenor. The three months tenor is most widely used as interest rate reference in Norwegian kroner. The model illustrates how various individual factors have contributed to the observed development in Nibor.

*The Statement is updated four times a year. This Statement includes data up to **1 March 2024**.*

Nibor – In short

Nibor shall reflect the interest rate level a bank requires for unsecured money market lending in Norwegian kroner to another bank. Nibor is calculated and published for the maturities of one week and one, two, three and six months.

The calculation of Nibor is based on submissions of data from a panel of six banks. When determining their submissions, the banks shall follow the “waterfall methodology” specified in the Nibor Panel Bank Code of Conduct.

Nibor

Nibor is derived from “Norwegian Interbank Offered Rate” and is the collective term for the set of Norwegian kroner money market interest rates administered by Norske Finansielle Referanser AS (NoRe).

Nibor is calculated and distributed by Global Rate Set Systems (GRSS). GRSS also acts as licensing agent for Nibor.

The underlying market

The Norwegian money market is characterised by liquidity being redistributed between the major market participants by using the currency swap market. This has been the situation all the time since the liberalisation of the credit markets in the 1980s. The use of currency swaps reflects the characteristics of the small, open Norwegian economy, with relatively large international engagements connected to trade in raw materials and shipping. In the aftermath of the financial crisis of 2007-08, the use of unsecured interbank market lending in Norwegian kroner contracted from an already low level, in line with the developments observed internationally.

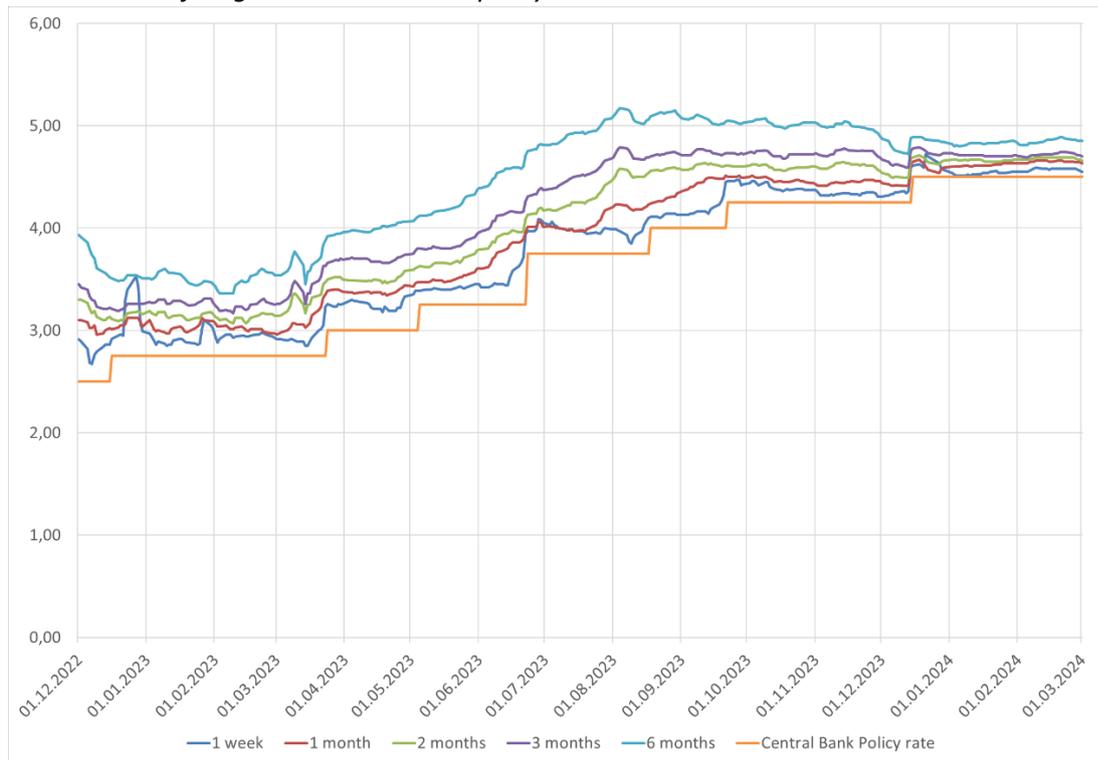

Market developments since the previous statement

Since November, the Norwegian money market has been rather calm. The primary factors influencing on Nibor during this period were

- 25 bp hike in the policy rate in December,
- affluent liquidity on the short end of the market, and
- year-end taxes and fees, which reflect the cost of capital over the year-end.

Inflation has declined internationally, and policy rates have been on hold. Hence, internationally, short term rates have been rather calm.

Chart 2 illustrates the spread between the highest and lowest submissions for one, three and six months Nibor. Taxes and fees affect the panel banks' cost of capital over the year-end, however in different ways dependent upon what tax regime the panel bank sorts under. Owing to that, the short end of the curve (1m) displays a rather high spread between the highest and lowest submission from the panel banks. in contrast, 3m and 6m spreads are relatively low.

Nibor input data

The lack of unsecured NOK-denominated interbank market transactions implies that submissions to Nibor, with few exemptions, are based on assessments of funding costs and bid/offer-spreads (type c submission). Statistics on the type of submissions received is presented in the table below. The table comprises reporting of background data since it was introduced in April 2020.

Period	Number of business days	Number of fixings	Number of submissions			
			Total	Level a	Level b	Level c
01.04.-31.12.20	189	945	5670	0	1	5669
2021	253	1265	7590	0	1	7589
2022	253	1265	7590	3	0	7587
2023	251	1255	7530	0	0	7530
01.01.-01.03.24	44	220	1320	0	0	1320

Brief introduction to the Nibor calculation methodology

The Nibor Panel Banks must be active in the market in which the redistribution of NOK liquidity takes place – in the relevant maturities and throughout the market’s trading hours – and have been active for a period of at least three months. The panel banks are also required to quote committing sales prices on Certificates of Deposits (CDs) or Commercial Papers (CPs) denominated in NOK, for the maturities 1, 2, 3 and 6 months. Minimum sales commitment is NOK 100 million for all maturities.

When determining its submissions, the individual bank shall follow the Nibor “waterfall methodology” priority of use of input data, summarized as follows:

- a. The bank’s own interbank lending transactions concluded with leading banks in the Norwegian Money Market with a minimum value of NOK 100 million at the same day as the Fixing. If none;
- b. the bank’s own borrowing transactions concluded from sales of CDs or CPs denominated in NOK with a minimum value of NOK 100 million at the same day as the fixing. If none;
- c. the bank’s committed price quotes on CDs or CPs denominated in NOK and expert judgements based on the bank’s weighted funding costs in USD and EUR, preferable prices from actual transactions. With exception for the one-week tenor, committed price quotes on CDs and CPs shall be given at least 50 percent weight in the calculations.

A spread shall be added to calculated borrowing rates, so that the submissions reflect the interest rates that the bank would charge for unsecured lending.

Nibor is fixed/calculated as trimmed averages of the interest rates submitted by the panel banks, where the lowest and the highest rates submitted are omitted. For more information about Nibor please refer to the Nibor Benchmark Statement and the Nibor Framework published on [NoRe’s website](#).

The Nibor Transparency model

Nibor is primarily based on level c submissions. The panel banks' underlying input to level c submissions may be used to illustrate how each separate factor has contributed to the calculation of Nibor; The "Nibor Transparency Model" calculates an alternative Norwegian Krone Offered Rate by applying the same methodology as the one which Nibor Panel Banks use to calculate their submissions of level c. However, the Nibor Transparency Model uses *the average* of each underlying data component reported by the banks. The derived rate based on averages is called "D-NOR". For more information about the Nibor Transparency Model please see explanation in box on the last page.

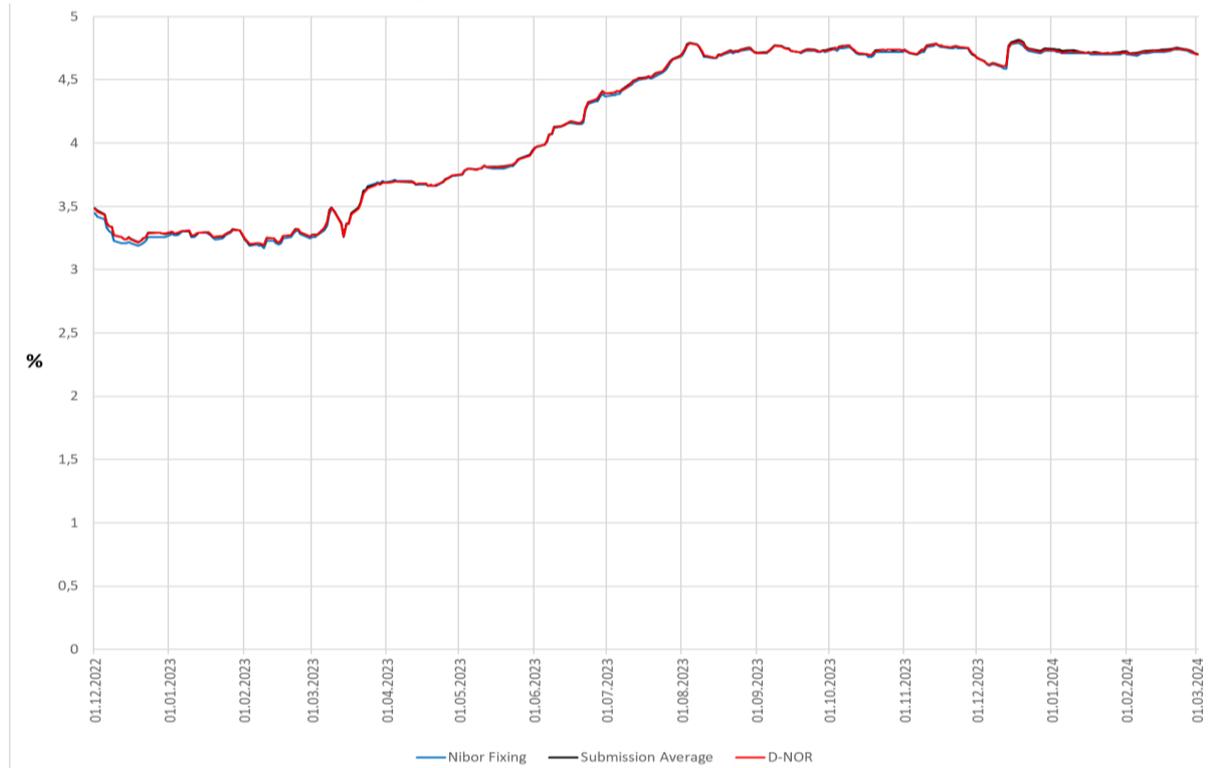

Nibor is calculated as a mean of Nibor submissions, omitting the lowest and the highest submission. This trimmed mean is normally not very different from a simple average of all submissions.

Underlying data for Nibor submissions

The Nibor Panel banks provide NoRe with background information on their submissions. This information is used as support for NoRe's control activity. The information to be provided depends on which level in the waterfall methodology the submissions have been based on. For transaction-based submissions (level a and b) information is to include whether or not interpolation or transactions with deviating maturity have been used. For non-transaction-based submissions (level c) the banks shall provide information about the underlying elements in their calculations (CD/CP quotes, foreign funding interest rates, foreign exchange spot and term rates) and the weights applied for each individual component. For level b and c submissions the banks also provide information on the spreads used for transforming borrowing rates into offered/lending rates.

The Nibor fixings, the averages of all submissions, and the D-NOR for the 3-month tenor is illustrated in Chart 3. The D-NOR and the average of all submissions have remained close to the Nibor fixings.

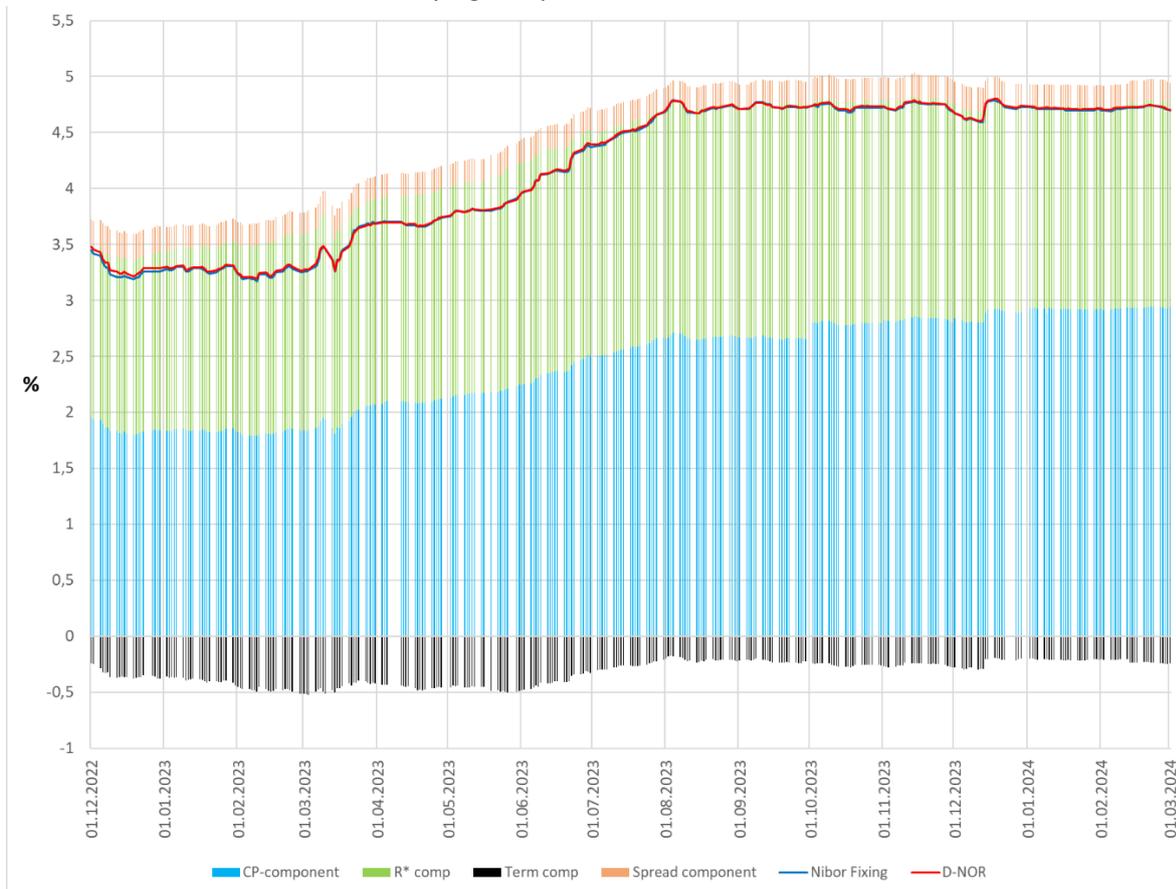

Chart 3. 3-month Nibor, the average of submissions and the D-NOR. Percent. 01.12.2022-01.03.2024

Source: NoRe

The Nibor Transparency Model calculations are presented in Chart 4. D-NOR and the corresponding Nibor fixing values are shown as lines. The underlying components are shown as stacked columns.

Chart 4. 3-month D-NOR and underlying components. Percent. 01.12.2022-01.03.2024

R*: Foreign lending costs, Term: Term premium from the foreign exchange market
Source: NoRe

The funding cost in NOK (blue) has increased slightly since November, while the weighted foreign funding cost in EUR and USD (green) is reduced. The “Term Component” (black area) is still reflecting that the weighted average rates of EUR and USD are higher than NOK rates. The average bid/offer spread (orange area) was unchanged at 21 bp in November and December, whereafter it was reduced to 19 bp during January and February.

The Nibor Transparency Model explained

The Nibor Transparency model calculates a Norwegian Krone Offered Rate based on background input data from the Nibor Panel Banks and the formula the banks use to determine their Nibor submissions of type c. This illustrative derived rate is called “D-NOR”.

The Nibor contributions of type c is the result of calculations using the following formula:

$$R_{PB} = r_{PBcp} * W_{PBcp} + (r_{PBeur} + t_{PBeur}) * W_{PBeur} + (r_{PBUSD} + t_{PBUSD}) * W_{PBUSD} + \text{margin}_{PB}$$

where

- “**R_{PB}**” is the Nibor submission of type c from the panel bank (“**PB**”),
- “**w**” is the weight used on each component, in sum equal to 1,
- “**r**” is interest rates from different markets,
- “**t**” is the term premia from the foreign exchange market expressed as an interest rate
- “**margin**” is the lending-borrowing margin
- “**cp**”, “**eur**” and “**usd**” is short for CP/CD, euro and US dollars respectively.

The transparency model isolates the individual components into sub-submissions representing the mean of received data for each individual factor.

- CP/CD-prices (expressed as interest rates): **r_{cp}**
- Foreign funding costs: **r_{eur}** and **r_{usd}**
- Foreign Exchange Term premia (expressed as interest rates): **t_{eur}** and **t_{usd}**
- Lending-borrowing margin/Spread: **margin**

Thereafter the offered rate (D-NOR) is calculated as a weighted average of these mean-sub-submissions using the averages of the banks’ calculation weights for each factor and the following formula:

$$D-NOR = r_{cp} * W_{cp} + (r_{eur} * W_{eur} + r_{usd} * W_{usd}) + (t_{eur} * W_{eur} + t_{usd} * W_{usd}) + \text{margin}$$

The results of the calculations are presented graphically, where

$$\text{CP component} = r_{cp} * W_{cp}$$

$$R^* \text{ comp} = r_{eur} * W_{eur} + r_{usd} * W_{usd}$$

$$\text{Term comp} = t_{eur} * W_{eur} + t_{usd} * W_{usd}$$

$$\text{Bid/ask spread component} = \text{margin}$$

The explanatory power of the model is somewhat limited when it comes to the part of Nibor movements being explained by changes in CD quotes. CD quotes are required to be given at least 50 percent weight in the Nibor submissions. However, the data indicates a clear historical correlation between the prices on CDs and NOK borrowing costs calculated from foreign funding costs and foreign exchange term premia (the sum of the Term and R* components), which reflects that both data sources indicate similar NOK funding cost developments.

The model uses information connected to level c-submissions only. As long as the majority of submissions continues to be based on level c, the model will illustrate the factors behind the movements in Nibor. However, if submissions of type a and b become frequent, the model’s explanatory power will be reduced.
